Helioseismology and the Changing Solar Dynamo

Rachel Howe
University of Birmingham
Synopsis

• Is the Sun changing?
• Helioseismology
• Mode frequency response to magnetic activity
• The torsional oscillation
• Implications for the solar dynamo
Is the Sun changing?

Bohm-Vitense (2007 *Astrophys. J.* 657, 486) – Stellar populations seem to lie along two branches on the rotation/cycle period plot, but the Sun lies somewhere in the middle.
Ratios of the predicted rotation period to the observed period.

Older stars rotate faster than expected — reduced magnetic braking?

“Our findings might suggest a fundamental change in the nature of ageing stellar dynamos, with the Sun being close to the critical transition to much weaker magnetized winds.”
Inside the Sun

- Prominence
- Coronal Streamer
- Photosphere (granules)
- Sunspot
- Core
- Radiative Zone
- Convective Zone
- Chromosphere
- Filament
- Coronal Hole
Inversions

• Combining information from different modes lets us build up a picture of properties at different depths.

• Rotational splittings ($m$) give us latitude information.
Frequency shifts with solar cycle

- BiSON, Mark I (Palle et al. 1989, Elsworth et al. 1990)

Howe et al. 2017

Chaplin et al. 2007
Figure 18. Frequency shift as a function of frequency, using frequencies from 1986 as a reference. The frequency dependence was obtained by averaging over modes in the range $4 \leq l \leq 140$ in degree. Data from 1988 are denoted by circles, data from 1989 by squares. From Woodard and Libbrecht (1991).
Quasi-biennial oscillation
(Broomhall et al. 2014, etc.)

Short-term variations in activity index and corresponding frequency change after main 11-year cycle removed.

Modulated by the solar cycle

Frequency response varies less steeply with frequency than for main cycle – deeper fields?
BiSON frequency shifts over three cycles

Proxies scaled to Cycle 22 – not such a good fit for Cycles 23 and 24
Things to bear in mind

• Modes of a given degree and frequency are trapped in a certain range of radii.
• Lower degree means deeper lower turning point
• Lower frequency means deeper upper turning point
• Frequency shifts dominated by magnetic activity in a thin layer near the surface.
BiSON frequency shifts over three cycles

Frequency shift vs activity proxy
Sensitivity vs frequency
Color-coded by degree $l$
Comparing medium- and low-degree frequency shifts

GONG, MDI/HMI, BBSO, and BiSON $l=0$
Frequency-binned, scaled shifts
Frequency Shifts - Summary

• Frequencies follow the activity level
• Low-degree, low frequency modes barely correlated with activity in the most recent two cycles – thinning magnetic layer?
• Medium-degree data does show correlation even at low frequencies.
• Both medium and low-degree data show slightly higher sensitivity to activity in Cycle 24 than Cycle 23 --- again, this could point to a thinning magnetic layer.
The torsional oscillation

- 23 years of observations from GONG, MDI, HMI.
- Mean subtracted over whole time series of 2d rotation inversions at each location.

Torsional Oscillation: Summary

• Comparing Cycle 24 with Cycle 23:
  • The higher latitudes rotated significantly slower
  • Poleward branch was present but weak
  • Faster-rotating bands at lower latitudes were stronger despite weaker activity.

• What about Cycle 25?
  • We are currently seeing signatures around 35 degrees.
  • New-cycle activity unlikely before 2020.
  • High-latitude rotation now even slower.
Conclusions

• Changes in the sensitivity of mode frequencies to activity hint at a thinner near-surface magnetic layer.
• Polar fields are weaker and this has been linked to slower rotation at high latitudes.
• Could these be signs that the solar dynamo is about to change to the weaker mode associated with aging stars? Maybe?
• Or it could `just’ be a grand minimum (or at least the end of a grand maximum?)
